In The United States Patent and Trademark Office

HONORABLE COMMISSIONER
FOR PATENTS
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

Information Disclosure Statement of "Reinforced Composite System for Constructing Insulated Concrete Structures" by Daniel D. Dunn et al.
Application No. 10/660,944, a continuation in part of Serial No. 09/803,205 filed March 09, 2001, now patent no. 6,647,686 titled "System for Constructing Insulated Concrete Structures."

Pursuant to the guidelines for Information Disclosure Statements set forth in 37 C.F.R. Sections 1.97-1.99 and MPEP Section 609, Applicant(s) submit(s) herewith patents, publications or other information of which he/she/they is/are aware, which may be material to the examination of this application and may be a duty of disclosure in accordance with 37 CFR 1.56.

A list of patent(s) and/or publication(s) is set forth on the attached Form "Information Disclosure Statement by Applicant."

The present invention discloses panels having reinforcement layers adhered to a foam plastic core. The tongue and groove are also wrapped with the same reinforcement or with preformed units. This totally encases and reinforces the foam core. The reinforcement layers strengthen the panels and protect the foam core from physical damage. The reinforced panels substantially reduce form deflection while pouring a wall, allowing concrete to be poured in higher lifts reducing the time and cost involved and virtually eliminates blowouts. Horizontal

stiffeners are disclosed embedded within and adhered to the foam plastic core and located at the midpoint of each panel. The horizontal stiffeners further reduce panel deflection by shortening the distance the foam core must span from the bottom to the top of each panel.

When using stucco or elastomeric exterior finishes on ICFS systems the joints between forms must be pre-treated by reinforcing and coating the joint to prevent the finish coat from cracking. On known art systems the pre-treatment causes unsightly bulges in the finish coat. The present invention discloses a tapered edge around the perimeter of the outside face of each panel which allows the pre-treatment to be installed flush with the surface of each panel.

The present invention discloses spreaders used to interconnect the form panels having first and second flanges connected by horizontal members with multiple formations. The formations in the topmost horizontal member are located in the top of said member, the topmost horizontal member being located substantially at the top of the flanges. The formations in the bottommost horizontal member are located in the bottom of said member, the bottommost horizontal member being located substantially at the bottom of the flanges. When the spreaders are stacked the formations in the top and bottom horizontal members compliment the formations of adjacent spreaders. The horizontal member from the upper spreader resting upon the horizontal member of the spreader below, the complimentary formations each forming half of a full circle, allowing wall reinforcement bars to be restrained within the circular formations. The applicants are not aware of any known art systems that totally restrain wall reinforcing bars in this method. The reinforcement retaining means provided in U.S. Patent No. 6,536,172 entitled "Insulating Construction Form and Manner of Employment for Same" issued to Amend Mar. 25, 2003, is typical of the methods used in the known art systems. The reinforcement seat is open on the top and while the retainer arms are meant to provide a snap fit it is impossible for them to accommodate large and small

reinforcement bars with the same web or tie member. The wall reinforcing must be tied to the web or tie members to prevent the reinforcement from popping out of the seat and becoming displaced while pouring concrete in the forms. The complimentary circular formations of the present invention totally restrain the reinforcement and one size of formation can be used to accommodate the most common reinforcement bar sizes.

The applicants are not aware of any method patented, disclosed, in use or known in the art that achieves the results of the above method disclosed in the present invention.

U.S. Patent No. 6,336,301 entitled "Concrete Form System Ledge Assembly and Method" issued to Moore, Jr. Jan 8, 2002, discloses a ledge assembly including a ledge panel, at least one ledge web member and a plurality of ledge attachment couplings. This provides a method of fabricating a concrete wall having one or more weight bearing ledge surfaces. The above referenced patent fails to show a method that achieves the results of the present invention in that the present invention discloses the use of a hinged form comprising opposing panels one of which has at least one horizontal pivotal section. The pivotal section allows the form panels to be shipped flat saving space. The panels may then be assembled on site by rotating the panel containing the pivotal section and installing bearing ledge connectors and spreaders to interconnect the panels thus providing a haunch usable as a bearing ledge. Hinged forms comprising opposed panels containing vertical pivotal sections may be used to form corners. Again the panels may be shipped flat saving space and rotated into position on site. The applicants are not aware of any existing method which achieves these results.

The below referenced patents are substantively cumulative, copies of these patents are not included in accordance with 37 CFR 1.98.

U.S. Patent No. 4,223,501 DeLozier Sep. 23,1980
